This genus usually has two convex deciduous sepals, four petals, and numerous stamens; the capsule is obovate, one-celled, opening under the crown of the stigma with short valves; the flowers are large and showy, usually red or white, but have only a short time. It consists of herbaceous plants abounding in milky juice. There are about fourteen species, chiefly found in Europe, North Africa, and Asia, but few of them are remarkable for any useful properties. *P. Rhoeas*, the common red poppy, so familiar a plant in this country, yields the syrup of red poppies of the British Pharmacopoeia. *P. somniferum* (the opium poppy) is common in gardens in Britain, and is probably a native of Asia Minor or of Central Asia. There are two distinct varieties, the red or violet flowered and black-headed, and the white-flowered with white seeds, called by some *P. officinale*. This poppy is cultivated on the Continent and elsewhere on account of its seeds, which yield a fixed oil much esteemed, and on account of the capsule, from which opium is obtained. Between the leaves grow the flower and the fruit, which is of the size of a melon. The juice is acid and milky, but the fruit when boiled is eaten with meat, like other vegetables. The juice of the unripe fruit is a most powerful and efficient vermifuge; the powder of the seed even answers the same purpose. The juice of the tree or its fruit, or an infusion of it, has the singular property of rendering the toughest meat tender, and this is even said to be effected by hanging the meat among the branches. 2. It is manufactured principally of vegetable fibre reduced to a pulp by means of water and grinding. Rags form the staple and most desirable material for paper-making, but upwards of 400 different materials are in use for the same purpose. Paper is also extensively made from old printed or written paper. Till the early part of the nineteenth century all paper was made by hand in moulds of various sizes. Of hand-made writing and drawing papers the largest size made called 'antiquarian' is 24 x 34 inches, and through numerous sizes it passes to the smallest called 'post'—14 x 12 inches. Machine-made paper is, however, made in a continuous sheet, while its breadth is only limited by the breadth of the machine on which it is made. All important newspapers or other periodicals are now printed on webs several miles in length, the paper not being cut till after it is printed. The machine-making of paper has to a great extent rendered obsolete the old distinctions of size which prevailed when only hand moulds were used, machines for cutting the 'webs' of paper accurately to any size being in use. The principal varieties of ordinary paper are—writing and printing papers, coarse papers for wrapping and other purposes, and blotting and filtering papers. While some useful kinds are the result of manipulations subsequent to the paper maker's work, as lithographic paper, copying paper, tracing paper, &c.—2. A piece, leaf, or sheet of paper.

It is now widely cultivated in tropical countries, and was at one time supposed to be a native of the East Indies. It grows to the height of 15 or 20 feet, with a soft herbaceous stem, naked nearly to the top, where the leaves form on every side on long footstalks. Between the leaves grow the flower and the fruit, which is of the size of a melon. The juice is acid and milky, but the fruit when boiled is eaten with meat, like other vegetables. The juice of the unripe fruit is a most powerful and efficient vermifuge; the powder of the seed even cures the same purpose. *Papaw* (Grove *Papaya*).

The juice of the tree or its fruit, or an infusion of it, has the singular property of rendering the toughest meat tender, and this is even said to be effected by hanging the meat among the branches. 2. It is manufactured principally of vegetable fibre reduced to a pulp by means of water and grinding. Paper from the staple and most desirable material for paper-making, but upwards of 400 different materials are in use for the same purpose. Paper is also extensively remade from old printed or written paper. Till the early part of the nineteenth century all paper was made by hand in moulds of various sizes. Of hand made writing and drawing papers the largest size made called "antiquarian" is 14½ x 24 inches, and through numerous sizes it passes to the smallest — called "post" 14½ x 12½ inches. Machine made paper is, however, made to a continuous sheet, while its breadth is only limited by the breadth of the machine on which it is made. All important newspapers or other periodicals are now printed on webs several miles in length, the paper not being cut till after it is printed. The machine-making of paper has to a great extent rendered obsolete the old distinctions of size which prevailed when only hand moulds were used, machines for cutting the "evens" of paper accurately to any size being in use. The principal varieties of ordinary paper are: writing and printing papers, coarse papers for wrapping and other purposes, and blotting and filtering papers, while some useful kinds are the result of manipulation consequent to the paper maker's work, as lithographic paper, copying paper, tracing paper, &c. 2. This genus usually has two convex deciduous sepals, four petals, and numerous stamens; the capsule is obovate, one-celled, opening under the crown of the stigma with short valves; the flowers are large and showy, usually red or white, but last only a short time. It consists of herbaceous plants abounding in milky juice. There are about fourteen species, chiefly found in Europe, North Africa, and Asia, but few of them are remarkable for any useful properties. *P. Rhoeas*, the common red poppy, so familiar a plant in this country, yields the syrup of red poppies of the British Pharmacopoeia. *P. somniferum* (the opium poppy) is common in gardens in Britain, and is probably a native of Asia Minor or of Central Asia. There are two distinct varieties, the red or violet flowered and black-headed, and the white-flowered with white seeds, called by some *P. officinale*. This poppy is cultivated on the Continent and elsewhere on account of its seeds, which yield a bland oil much esteemed, and on account of the capsules, from which opium is obtained. On the latter account it is extensively cultivated in Turkey and Asia Minor, Egypt, Persia, and India. See **OPIMUM**.

It is now widely cultivated in tropical countries, and was at one time supposed to be a native of the East Indies. It grows to the height of 15 or 20 feet, with a soft herbaceous stem, naked nearly to the top, where the leaves lump on every side on long footstalks. Between the leaves grow the flower and the fruit, which is of the size of a melon. The juice is acid and milky, but the fruit when boiled is eaten with meat, like other vegetables. The juice of the unripe fruit is a most powerful and efficient vermifuge; the powder of the seed even answers the same purpose. The juice of the tree or its fruit, or an infusion of it, has the singular property of rendering the toughest meat tender, and this is even said to be effected by hanging the meat among the branches. *2.* The papaw of North America is *Destinea* (Tridax), nat. order *Compositae*; it produces a sweet edible fruit.

Paper (pă-păr), *n.* [*Fr.* *papier*, *It.* *carta*, from *L.* *papyrus*, or *papyrus*, an Egyptian reed, from the lower part of which a kind of writing paper was anciently made in Egypt.] *1.* A thin and flexible substance of various colours, but most commonly white, used for writing and printing on, and for various other purposes. It is manufactured principally of vegetable fibre reduced to a pulp by means of water and grinding. Rags form the staple and most desirable material for paper-making, but upwards of 400 different materials are in use for the same purpose. Paper is also extensively made from old printed or written paper. Till the early part of the nineteenth century all paper was made by hand in moulds of various sizes. Of hand-made writing and drawing papers the largest size made is called 'antiquarian' — is 24 x 30 inches, and through superfine sizes it passes to the smallest — called 'pott' — 14 x 12 inches. Machine-made paper is, however, made in a continuous sheet, while its breadth is only limited by the breadth of the machine on which it is made. All important newspapers or other periodicals are now printed on webs several miles in length, the paper not being cut till after it is printed. The machine-making of paper has to a great extent rendered obsolete the old distinctions of size which prevailed when only hand moulds were used, machines for cutting the 'webs' of paper accurately to any size being in use. It consists of herbaceous plants abounding in milky juices. There are about fourteen species, chiefly found in Europe, North Africa, and Asia, but few of them are remarkable for any useful properties. *P. Rhæas*, the common red poppy, so familiar a plant in this country, yields the syrup of red poppies of the British Pharmacopoeia. *P. somniferum* (the opium poppy) is common in gardens in Britain, and is probably a native of Asia Minor or of Central Asia. There are two distinct varieties, the red or violet flowered and black-seeded, and the white-flowered with white seeds, called by some *P. officinale*. This poppy is cultivated on the Continent and elsewhere on account of its seeds, which yield a bland oil much esteemed, and on account of the capsules, from which opium is obtained. On the latter account it is extensively cultivated in Turkey and Asia Minor, Egypt, Persia, and India. See OPIUM.

It grows to the height of 18 or 20 feet, with a soft herbaceous stem, naked nearly to the top, where the leaves issue on every side on long footstalks. Between the leaves grow the flower and the fruit, which is of the size of a melon. The juice is acid and milky, but the fruit when boiled is eaten with meat, like other vegetables. The juice of the unripe fruit is a most powerful and efficient vermifuge; the powder of the seed even answers the same purpose. The juice of the tree or its fruit, or an infusion of it, has the singular property of rendering the toughest meat tender, and this is even said to be effected by hanging the meat among the branches. 2. The papaw of North America is *Asimina triloba*, nat. order Annonaceae; it produces a sweet edible fruit.

1. A thin and flexible substance of various colours, but most commonly white, used for writing and printing on, and for various other purposes. Rags form the staple and most desirable material for paper-making, but upwards of 400 different materials are in use for the same purpose. Paper is also extensively remade from old printed or written paper. Till the early part of the nineteenth century all paper was made by hand in moulds of various sizes. Of hand-made writing and drawing papers the largest size made—called 'antiquarian'—is 6½ x 30½ inches, and through numerous sizes it passes to the smallest—called 'post'—15½ x 12½ inches. Machine-made paper is, however, made in a continuous sheet, while its breadth is only limited by the breadth of the machine on which it is made. All important newspapers or other periodicals are now printed on webs several miles in length, the paper not being cut till after it is printed. The machine-making of paper has to a great extent rendered obsolete the old distinctions of size which prevailed when only hand moulds were used; machines for cutting the 'webs' of paper accurately to any size being in use. The principal varieties of ordinary paper are—writing and printing papers, coarse papers for wrapping and other purposes, and blotting and filtering papers, while some useful kinds are the result of manipulations subsequent to the paper-maker's work, as lithographic paper, copying paper, tracing paper, &c.—2. In *gram.* a part of speech, so called because it partakes of the character both of a verb and an adjective. The participle differs from the adjective in that it implies time, and therefore applies to a specific act, whereas the adjective designates only an attribute, as a habitual quality or characteristic, without regard to time. Thus 'Jupiter tonans' may be translated either 'Jupiter when thundering' or 'Jupiter who is in the habit of thundering,' that is, 'thundering Jupiter.' In the former case *tonans*, as well as its English equivalent, is a participle; in the latter both are adjectives. When we say, 'he has learned his lesson,' we have regard to a specific act done at a certain time; but in the phrase 'a learned man,' *learned* designates a habitual quality. In the former case *learned* is a participle; in the latter, an adjective. There are two participles in English: the present—ending in *-ing*, and the past—ending, in regular verbs, in *-ed*. The verbal noun in *-ing*, often said to be the present participle used as a noun, in reality represents the Anglo-Saxon termination *-ung*, of verbal substantives. Participles often lose their original verbal properties and become adjectives; as, *will-ing*, in the phrase, a *willing* heart; *engag-ing*, as *engaging* manners; *accomplished*, as an *accomplished* orator.—2. The statute also allows that, in place of depositing a provisional specification on making application for letters patent, as was necessary under previous acts, the petitioner may at once file a complete specification of his invention, by which he secures the right, in addition to a protection for six months, of proceeding at law against any person who may infringe his claim, even before the grant is actually made, and which may never be issued. Pendulum (pen'du-lum), *n.* [Lat. what hangs down, from L. *pendulus*, hanging down, from *pendere*, to hang.] A body so suspended from a fixed point as to move to and fro by the alternate action of gravity and momentum. The time occupied by each oscillation or swing is counted from the time of the descent of the pendulum from the highest point on one side till it attains the highest point on the opposite side. The point A, about which the pendulum A B moves, is called the point of suspension or centre of motion, the line CD, parallel to the horizon, is the axis of oscillation, and the arc B A B is called the arc of vibration. Pendulums receive different denominations, according to the materials of which they are composed, or the purposes they are intended to answer. A simple weight attached by a string, &c., is called a *simple* pendulum; but the common clock pendulum usually consists of a rod of metal or wood, suspended so as to move freely about the point of suspension, and having a flat circular piece of brass or other heavy material called a bob attached to its lower end. The metal rod, however, is subject to variations in length in consequence of changes of temperature, and as the accuracy of the pendulum considered as a regulating power depends upon its always maintaining the same length, various contrivances, under the name of compensation pendulums, have been adopted in order to counteract the effects of changes of temperature. These take particular names, according to their forms and materials, as the *gridiron* pendulum, the *mercurial* pendulum, the *lunar* pendulum, &c. The *gridiron* pendulum is composed of any odd number of rods, so connected that the expansion or contraction of the one set of them is counteracted by that of the other. The *mercurial* pendulum consists of one rod with a vessel containing mercury at the lower end, so adjusted in quantity that whatever alterations take place in the length of the pendulum, the centre of oscillation remains the same, the mercury ascending when the rod descends, and vice versa. The pendulum is of great importance as the regulating power of clocks. Our clocks are nothing more than pendulums, with wheel-work attached to register the number of vibrations, and with a weight or spring having force enough to counteract retarding effects of friction and the resistance of the air, and when the pendulum is so adjusted as to beat or vibrate 60 x 60 = 3600

times in an hour, it is called a *seconds* pendulum. The length of such a pendulum in the latitude of London, and at the level of the sea, is 39 1/4 inches nearly, or more accurately 39 1/8 inches; but as the force of gravity diminishes towards the equator and increases towards the poles, owing to the figure of the earth, the *seconds* pendulum must be shortened in lower latitudes and lengthened in higher. The length of a pendulum is the distance between the point of suspension and the centre of oscillation. (See **CENTER**.) Besides its use as a regulator of clocks, the pendulum is applied to determining the relative force of gravity at different places, and also to determine the exact figure of the earth.

Prov. *pin-wing*, is equivalent to *pen-wing* or the part of the wing that carries the *pen* or quill. A common name for several birds of the genus *Apesodytes*, family *Apesodytidae*, or *Apesodytidae*, allied to the swan and gull-like.

The wings are rudimentary, destitute of quill-feathers, and covered with a scaly skin; they are useless as organs of flight, but are effective aids in diving and swimming, and on land are often used in the manner of fore-legs. The legs are placed at the hinder extremity of the body, and the birds assume an erect attitude when on land, the toes are completely webbed. The body is covered with short close-set feathers, the neck is moderately long; the head small, the bill of moderate length, the tail short. Perception is that act of the mind, or rather a passion or impression, whereby the mind becomes conscious of anything; as when I feel hunger, thirst, cold, or heat. *Watts.*

2. In *philos.* the faculty of perceiving; the faculty or peculiar part of man's constitution, by which he has knowledge through the medium or instrumentality of the bodily organs, or by which he holds communication with the external world. It is distinguished from *conception* by the circumstance that its objects are in every instance supposed to have an actual existence. We may *conceive* things that have no reality, but we are never said to *perceive* such things. Perception differs from *consciousness* in that it takes cognizance only of objects without the mind. We *perceive* a man, a horse, a tree; when we think or feel, we are conscious of our thoughts and emotions. It is further supposed in *perception* that the objects of it are present. We can remember former objects of perception, but we do not perceive them again until they are once more present. The term *perception*, however, is sometimes analogically employed in common speech in reference to truths, the evidence of which is certain. Thus we may *perceive* the truth of a mathematical proposition. —3. † Notion; idea.

In speaking of the perpetual motion, it is to be understood that from the forces by which motion may be produced we are to exclude air, water, and other natural agents, as heat, atmospheric changes, &c. In speaking of the perpetual motion, it is to be understood that from the forces by which motion may be produced we are to exclude air, water, and other natural agents, as heat, atmospheric changes, &c. Correctly defined, a **perspective delineation** is a section, by the plane or other surface on which the delineation is made, of the cone of rays proceeding from every part of the object to the eye of the spectator. It is intimately connected with the arts of design, and is particularly necessary in the art of painting, as without a correct observance of the rules of perspective no picture can have truth and life. Perspective alone enables us to represent foreshortenings with accuracy, and it is requisite in delineating even the simplest positions of objects. Perspective may be divided into two branches—**linear** and **aerial**. **Linear perspective** has reference to the position, form, magnitude, &c., of the several lines or contours of objects. The outlines of such objects as buildings, machinery, and most works which consist of geometrical forms, or which can be reduced to them, may be most accurately obtained by the rules of linear perspective, since the intersection with an interposed plane of the rays of light proceeding from every point of such objects may be obtained by the principles of geometry. Linear perspective includes the various kinds of projections, as **zenographic**, **orthographic**, **ischographic**, **stereographic** projections, &c. Aerial perspective teaches how

to give due diminution to the strength of light, shade, and colours of objects according to their distances, and the quantity of light falling on them, and to the medium through which they are seen. — **Isometrical perspective**, a kind of perspective on the principles of orthographic projection, by which solids of the form of rectangular parallelipeds, or such as are reducible to this form, can be presented with their three pair of planes in one figure, which gives a more intelligible idea of their form than can be done by a separate plan and elevation. At the same time, this method admits of their dimensions being measured by a scale as directly as by the usual mode of delineation. As applied to machinery it gives the elevation and ground-plan in one

view. It is considered, for such purposes, to be preferable to the methods in common use, as it is easier and simpler in its appli-

2. Cause of disquiet. 'O polished *perturbation*, golden care!' *Shak*.—**Perturbations of the planets**, in *astron.* their orbital irregularities or deviations from their regular elliptic orbits. These deviations arise, in the case of the primary planets, from the mutual gravitations of these planets towards each other, which derange their elliptic motions round the sun; and in that of the secondaries, partly from the mutual gravitation of the secondaries of the same system, similarly deranging their elliptic motions round their primary, and partly from the unequal attraction of the sun on them and on their primary. The forces which cause these perturbations or deviations are called the *perturbing* forces, and the determination of their effect on each orbit is the great problem of physical astronomy. The planets are subject to two kinds of perturbations; one kind, depending upon their positions with regard to each other, begins from zero, increases to a maximum, decreases, and becomes zero again when the planets return to the same relative positions. All these changes being accomplished in comparatively short periods, are denominated *periodic inequalities*. The inequalities of the other kind are entirely independent of the relative positions of the planets. They depend upon the relative positions of the orbits alone, whose forms and places in space are thus altered by very minute quantities in immense periods of time, and the deviations are therefore called *secular inequalities*. Of the planetary perturbations, the most important in a practical point of view are those which arise from the mutual attractions of the three bodies, the sun, the earth, and the moon.

Last came the interpreter, in whose slowly relaxing grasp we still lie—the heavy-handed Protestant *Philistine*—sincere, gross of perception, prosaic, he saw in Paul's mystical idea of man's investiture with the righteousness of God nothing but a strict legal transaction, and reserved all his imagination for Hell and the New Jerusalem and his foretaste of them. *Matt. Philology (fī-lō-lō-jī), *n.* [*Gr. philologia*, from *philos*, to love, and *logos*, a word.] 1. In the ancient Greek sense, the love of learning and literature; also, the study of language and literature.—2. Criticism; grammatical learning. This is Johnson's definition, but the word is seldom used in this sense now. It is more properly defined as the study of languages in connection with, and as a means to the whole moral and intellectual action of different peoples. It is sometimes made to include rhetoric, poetry, history, and antiquities; sometimes it is regarded as more especially embracing the study of the classical languages, literature, and history. See extract below.—3. The science of language; linguistic science; linguistics. This is now a common signification of the term, but the qualified title of *comparative philology* is preferable to express this meaning. See extract.

Philology, whether classical or oriental, whether treating of ancient or modern, of cultivated or barbarous languages, is an historical science. Language is here treated simply as a means. The classical scholar uses Greek or Latin, the oriental scholar Hebrew or Sanskrit, or any other language, as a key to the understanding of the literary monuments which bygone ages have bequeathed to us as a spell to raise from the tomb of time the thoughts of great men in different countries, and as a means ultimately to trace the social, moral, intellectual, and religious progress of the human race. . . . In *comparative philology* the case is totally different. In the science of language languages are not treated as a means; language itself becomes the sole object of scientific inquiry. Dialects which have never produced any literature at all, the jargons of savage tribes, the clicks of the Hottentots, and the vocal modulations of the Indo-Chinese are as important, nay, for the solution of some of our problems, more important than the poetry of *Homer* or the prose of *Cicero*. We do not want to know languages, we want to know

language; what language is, how it can form an instrument or an organ of thought; we want to know its origin, its nature, its laws, and it is only in order to arrive at that knowledge that we collect, arrange, and classify all the facts of language that are within our reach. *Max Müller.*

Philosophy (fī-lō-sō-fēr'ik), n. [Or *philosophia*, from *philos*, love, and *sophia*, wisdom.] 1. The love of wisdom, or search after wisdom. But in modern acceptation philosophy may be defined as the universal science which aims at an explanation of all the phenomena of the universe by ultimate causes; the knowledge of phenomena as explained by, and resolved into, causes and reasons, powers and laws. When applied to any particular department of knowledge, it denotes the collection of general laws or principles under which all the subordinate phenomena or facts relating to that subject are comprehended. Thus that branch of philosophy which treats of God, &c., is called *theology*; that which treats of nature is called *physics* or *natural philosophy*; that which treats of man is called *ethics*, or *moral philosophy*; that which treats of the mind is called *intellectual* or *mental philosophy*, or *metaphysics*. The terms *philosophy of history*, *philosophy of manufactures*, and other such terms are also used. All classes of objects, indeed, which can occupy the mind may have something in common, called their philosophy, which philosophy is nothing else than the general expression for that effort of the mind whereby it strives, pursuant to its laws, to reduce its knowledge to the form of ultimate truths or principles, and to determine the immutable relations which exist between things as it conceives them. The philosophy which comprises within itself all philosophies is that which labours to determine the laws or ultimate principles in obedience to which the mind itself operates; that which seeks to discover the ultimate foundation of all that it knows or conceives; to discover what it is, and what is its relation to all things, and so it strives to form a system out of all such ultimate laws or principles. Such a system may be called a philosophy in the absolute sense of the term, in which it is nearly equivalent to metaphysics.

Philosophy has been defined—the science of things divine and human, and the causes in which they are contained,—the science of effects by their causes;—the science of sufficient reasons;—the science of things possible, inasmuch as they are possible,—the science of things evidently deduced from first principles;—the science of truths amiable and abstract;—the application of reason to its legitimate objects;—the science of the relations of all knowledge to the necessary ends of human reason;—the science of the original form of the ego, or mental self;—the science of science;—the science of the absolute;—the science of the absolute indifference of the ideal and real. *Sir W. Hamilton.*

Hence the phoenix

often serves as an emblem of immortality. The phoenix is always drawn by the heralds in flames.

And glory, like the phoenix, midst her flames, Exalts her colors, blazes, and expires. *Byron.*

Phonograph (fō-nō'graf), *n.* (See *PHONOGRAPHY*) 1. A type or character for expressing a sound, a character used in phonography. 2. An instrument by means of which sounds can be permanently registered, and afterwards reproduced from the register. It consists essentially of a curved tube, one end of which is fitted with a mouthpiece, while the other end (about 2 inches in diameter) is closed in with a diaphragm of exceedingly thin metal. Connected with the centre of this diaphragm is a steel point, which, when the sounds are projected on the disc from the mouthpiece, vibrates backwards and forwards. This part of the apparatus is adjusted to a cylinder which rotates on a horizontal axis. On the surface of the cylinder is cut a spiral groove, and on the axis there is a spiral screw of the same pitch, which works in a nut. When the instrument is to be used a piece of tin foil is gummed round the cylinder, and the steel point is adjusted so as to be just touching the tin foil, and above the line of the spiral groove. If some words are now spoken through the mouthpiece, and the cylinder kept rotating either by the hand or clock work, a series of small marks are made on the foil by the vibratory movement of the steel point, and these markings have all an individual character of their own, due to the various sounds addressed to the mouthpiece. The sounds thus registered are reproduced by approaching the diaphragm and its steel point towards the tin foil as at first commencing, at the point where it was when the cylinder originally started. The indentations previously made now cause the steel point to rise or fall or otherwise move as the markings pass under it, and the result is that the diaphragm is thrown into a state of vibration exactly corresponding to the movements induced by the markings, and thus effects the air around so as to produce sounds, and these vibrations being exactly similar to those originally made by the voice, necessarily reproduce those sounds to the ear as the words at first spoken. These marked strips of foil may be posted to any person with whom the speaker wishes to correspond, and who must of course have a machine similar to that of the sender. The contents of the strips may be reproduced at any length of time, and repeated until the markings become effaced.

Phosphorescence (fōr'tor-ēns), *n.* The state or quality of being phosphorescent; the property which certain bodies possess of becoming luminous without undergoing combustion. *Phosphorescence* is sometimes a chemical, sometimes a physical action.

When chemical, it consists essentially in slow oxidation attended with evolution of light, when physical, it consists in the emission of light previously absorbed, or in the transformation of heat rays into light rays. The phosphorescence of the sea is produced

by the scintillating or phosphorescent light emitted from the bodies of certain marine animals, and is well seen on the surface of the ocean at night. See *extract*.

The diffused luminosity of the sea is mainly due to the *Noctiluca miliaris*; but its partial luminosity is due to various phosphorescent animals, amongst which are the *Physalia physalis* (the Portuguese man-of-war), *Medusa*, *Tunicata*, *Annelides*, &c. The cause of phosphorescence is variously stated, it being supposed very generally to be the result of a process of slow combustion analogous to that which takes place in phosphorus when exposed to the atmosphere. Upon the whole, however, it appears that the phenomenon is a vital process, consisting essentially in the conversion of nervous force (vital energy) into light; just as the same forces can be converted by certain fishes into electricity. *H. A. Nicholson.*

Phosphorescent (fos-to-res-ent), *a.* Shining with a faint light or luminosity like that of phosphorus; luminous without sensible heat. Various animals are phosphorescent, as the glowworm, the phosphorescent seapen (*Pennatula phosphorea*), and the brilliant pyrosoma. Fish also possess this property in a remarkable degree. A number of mineral substances exhibit the same property, as chloride of calcium, anhydrous nitrate of lime, some carbonates and sulphates of baryta, strontia, and lime, the diamond, some varieties of fluor-spar, apatite, borax, and many other substances. Some mineral bodies become phosphorescent when strongly heated, as a piece of lime. The same property is observable in decayed wood. See **PHOSPHORESCENCE**.

—**Phosphoric acid** (PH_3O_4), an acid usually obtained by burning phosphuretted hydrogen in atmospheric air or oxygen. It is also produced by the oxidation of phosphorous acid, by oxidizing phosphorus with nitric acid, by the decomposition of apatite and other native phosphates, and in various other ways. It is tribasic, forming three distinct classes of metallic salts, and the three atoms of hydrogen may in like manner be replaced by alcohol radicals, forming acid and neutral ethers. Phosphoric acid is used in medicine in the form of solution, constituting the dilute acid of the Pharmacopoeia. It is peculiarly suited to disordered states of the mucous surfaces, and also to states of debility, characterized by softening of the bones.

Phosphorous acid exists usually in the form of a thick uncrystallizable syrup, but it may also be obtained crystallized. This acid is *di-basic*, forming two series of metallic salts, named respectively *neutral* and *acid phosphites*. — **Phosphorous anhydride** (P_2O_3), a soft, white, readily volatile powder, prepared by burning phosphorus in a limited supply of air.

Phosphorus (fos-to-ru-s), *n.* [L. *phosphorus*, Gr. *phosphoros*, the morning-star, lit. light-bringer, from *phôs*, light, and *phêrô*, to bring. The chemical substance has this name from its character.] 1. The morning-star; Phosphor (which see). — 2. Sym. P. At. wt. 31; sp. gr. 1.826. A solid non-metallic combustible substance, hitherto undecomposed, occurring chiefly in combination with oxygen, calcium, and magnesium, in volcanic and other rocks, whose disintegration constitutes our fertile soils. It exists also in the plants used by man as food, and is a never-failing and important constituent in animal structures. It was originally obtained from urine; but it is now manufactured from

bones, which consist in part of phosphate of lime. Common phosphorus when pure is almost transparent and colourless. At common temperatures it is a soft solid, easily cut with a knife, and the cut surface has a waxy lustre; at 108° it fuses, and at 550° is converted into vapour. It is soluble, by the aid of heat, in naphtha, in fixed and volatile oils, in the chloride of sulphur, sulphide of carbon, and sulphide of phosphorus. It is exceedingly inflammable. Exposed to the air at common temperatures it undergoes slow combustion, emits a white vapour of a peculiar alliaceous odour, appears luminous in the dark, and is gradually consumed. On this account phosphorus should always be kept under water. A very slight degree of heat is sufficient to inflame phosphorus in the open air. Gentle pressure between the fingers, friction, or a temperature not much above its point of fusion, kindles it readily. It burns rapidly even in the air, emitting a splendid white light, and causing intense heat. Its combustion is far more rapid in oxygen gas, and the light far more vivid. The product of the perfect combustion of phosphorus is phosphorous pentoxide (P_2O_5), a white solid which readily takes up water, passing into phosphoric acid (which see). Phosphorus may be made to combine with most of the metals, forming compounds called *phosphides*; when dissolved in fat oils it forms a solution which is luminous in the dark. It is chiefly used in the preparation of lucifer-matches, and also in the preparation of phosphoric acid. It is of all stimulants the most powerful and diffusible, but on account of its activity highly dangerous. It can be safely administered as a medicine only in extremely minute doses, and with the utmost possible caution. Phosphorus presents a good example of allotropy (see **ALLOTROPY**), in that it can be exhibited in at least one other form, known as *red* or *amorphous phosphorus*, presenting completely different properties from common phosphorus. This variety is produced by keeping common phosphorus a long time slightly below the boiling-point. It is a red, hard, brittle substance, not fusible, not poisonous, and not readily inflammable, so that it may be handled with impunity. When heated to the boiling-point it changes back to common phosphorus. — **Bolognian phosphorus**, calcined native sulphate of barytes, one of the most powerful of the solar phosphoric substances. When heated with charcoal, and exposed to the sun's rays, it emits light in the dark for some hours. — **Phosphorus bottle**, (a) a contrivance for obtaining instantaneous light. The light is produced by stirring a piece of phosphorus about in a dry bottle with a hot wire, and introducing a sulphur match. It is now superseded by lucifer matches and similar contrivances. (b) A 1-oz. phial containing 12 grains phosphorus melted in 4 oz. olive-oil. On this being uncorked in the dark it emits light enough to read the dial of a watch, and it will retain this property for several years if not too frequently used. — **Phosphorus paste**, a poisonous composition for the destruction of vermin, as rats, mice, cockroaches, &c.

Phosphuret (fos-to-ret), *n.* The name formerly given to phosphide (which see).

Phosphuretted (fos-to-ret-ed), *a.* Combined with phosphorus. — **Phosphuretted hydrogen** (PH_3), a gas procured by boiling phosphorus in a solution of a caustic alkali. The gas which arises is spontaneously inflammable; and during its combustion there are formed water and phosphoric acid. It is colourless, and has a disagreeable smell resembling that of onions. When mixed with air or oxygen gas it explodes at a temperature of 300°. It is produced by the decomposition of animal substances. When this gas is cooled below zero (C.) it deposits a liquid phosphide of hydrogen; the gaseous phosphide remaining is no longer spontaneously inflammable.

A mixture consisting of a solution of gelatine in water and a saturated solution of bichromate of potash is poured on the plate and allowed to dry. It is then placed in a printing frame with the object it is desired to copy laid on it, and exposed to the action of light. Hydrochloric acid is next poured on the plate, which attacks only the parts which the light has not acted on, thus etching in the design of the object superimposed. It is the invention of Mr. Fox Talbot.

Photography (fô-to-grä-fi), *n.* [Gr. *phôs*, *phôtos*, light, and *gräphô*, to describe.] 1. The science of the action of light on bodies; the principles of physics and chemistry which relate to the production of pictures by the action of light. — 2. The art of delineating objects by the action of light. The name, however, as applied to the process of producing pictures by the sun's rays, rests on a misconception. The true light-giving rays of the sun have no influence in altering the chemical condition of bodies and thereby of producing those changes in their colour on which photography depends. Recent investigations prove that these changes are produced to some extent by the feebly luminous blue and violet rays of the spectrum, but chiefly by other rays which are absolutely dark or invisible. The epithet *actinic*, *fluorescent*, or *chemical* has been applied to

these rays. (See ACTINISM.) The principle on which photography depends reaches back to the time of the alchemists, who discovered that chloride of silver exposed to the sun's rays became black. Wedgwood and Davy in 1802 attempted to apply this fact to artistic purposes by throwing the shadow of an object on a sheet of white paper, or, preferably, of leather, covered with a solution of nitrate of silver and exposed to the sun's rays, but they were unable to fix the pictures. About 1814 M. Niepce, in France, discovered a method of producing pictures on plates of copper or pewter, covered with a sensitive resinous substance called bitumen of Judea, and also of rendering them permanent. This process he called *heliography*. M. Niepce associated himself with M. Daguerre, who elaborated from his process the very beautiful one which bears his name. (See DAGUERRETYPE.) This process has been superseded by two processes, viz. the *calotype process* of Mr. Fox Talbot, first patented in 1841, who revived Mr. Wedgwood's process of obtaining pictures on sensitized paper (see CALOTYPE), and the *collodion process*, first suggested by M. Le Grey, of Paris, and introduced by Mr. Archer in 1850. (See COLLODION.) Calotype and collodion photographs may be *negative* or *positive*. *Negative* photographs exhibit the lights and shades contrary to nature, that is, the lights dark and shades white; *positive* photographs exhibit them in accordance with nature. To produce a *positive*, the negative is placed on the sensitive surface of a sheet of paper, and a piece of glass pressed on both to insure contact. The sunlight penetrates the negative and darkens the parts of the underlying paper opposite the lights of the picture, whilst the parts opposite the opaque parts of the picture (the lights of nature) are protected. The process for obtaining a *positive* from a negative is called *printing*. In the *Niepcotype process* albumen is used as the basis of the film in place of collodion. Many modifications are constantly being introduced into photography, as the carbon process, popularized by Mr. Swan of Newcastle, whose plan was to prepare a solution of gelatine and bichromate of potash (the latter being the sensitizing agent), mixed with some black pigment, and apply the mixture as a coating to a sheet of paper, and print his positives on the black oak, or *tisane* as it is called, thus produced. The *autotype process*, invented by Mr. Johnson, is a more simple and ready method of carbon-printing than the carbon process proper, but the principles involved are the same. Various modes of multiplying photographic pictures by what is termed *photo-lithography* have been successfully tried. For a mode of multiplying pictures by *litho-photography* from a hardened tissue, similar to that employed in the carbon process, see under HELIOTYPE. In Mr. Woodbury's engraving process the hardened tissue is brought into contact with a plate of type metal under considerable pressure. The plate takes the impression of the relief, and pictures are printed from it instead of from the raised tissue.

All such instruments have for essential purpose the determina-

tion of the relative distances at which two sources produce equal intensities of illumination. One of the most common photometers is that of Bunsen, which consists of a screen of white paper with a grease-spot in its centre. The lights to be compared are placed on opposite sides of this screen, and their distances are so adjusted that the grease-spot appears neither brighter nor darker than the rest of the paper, from whatever side it is viewed. When the distances have not been correctly adjusted, the grease-spot will appear darker than the rest of the paper when viewed from the side on which the illumination is most intense, and lighter than the rest of the paper when viewed from the other side. The intensities of the two lights are to one another as the squares of the distances from the screen at which they must be placed in order that the grease-spot may appear neither brighter nor darker than the rest of the paper.

Photo-sculpture (fō-tō-skulp-tūr), *n.* [Gr. *phōs*, *phōtos*, light, and *E. sculpture*.] The process of sculpturing statuettes, medallions, and the like, by the aid of photography. The person whose likeness is to be taken is placed in the centre of a circular room, in the wall of which there are twenty-four equidistant circular holes only large enough to permit the action of a camera lens through each, while in a dark passage outside the wall there are twenty-four cameras, each of which receives the image of that portion of the person towards which its lens is directed. The subject is thus photographed all round. The pictures thus received are then so arranged that in a neighbouring room they can be projected in succession by means of a magic lantern on a transparent screen. The sculptor works behind this screen on a piece of modelling clay, turning it round as he works, and copying the figures produced on the screen successively by means of a pantograph, which has its reducing point armed with a moulding or cutting tool, so that, as the longer arm is tracing each figure on the screen the shorter one is reproducing it on the clay.

According to Kirchhoff the sun's photosphere is either solid or liquid, and is surrounded by an extensive non-luminous atmosphere, composed of gases and vapours of the substances incandescent in the photosphere.

But the term is now restricted to a doctrine founded on a presumed knowledge of the functions of different portions of the brain obtained by comparing their relative forms and magnitudes in different individuals with the propensities and intellectual powers which these individuals are found respectively to possess. The doctrine which is the basis of phrenology was first propounded by Dr. Gall, a physician of Vienna, and subsequently by Dr. Spurzheim, Dr. A. Combe, George Combe, and others. The doctrine is based on the idea that the brain is an aggregation of parts or organs, and that each organ has a distinct and separate function in the evolution of mind or mental acts. The faculties are usually divided into two orders—*feelings* and *intellect*, or *affective* and *intellectual faculties*. The feelings are divided into two genera—the propensities and the sentiments; while the intellectual faculties are divided into the perceptive or knowing and the reflective faculties. In the subjoined figures the different organs (most of them double) are marked out and numbered, according to the system of Spurzheim. Frey and Hitzig in Germany and Ferriar and others in England have endeavored to prove experimentally that certain functions are localized in certain parts of the brain, but their experiments are not conclusive.

Pianoforte (pi-an-o-for-té), n. [It. *piano* (L. *planus*), soft, *ita*, piano, smooth, and *forte* (L. *fortis*), strong.] A musical metal-stringed instrument of the keyed species. The name was given to it to distinguish it from its immediate predecessors, the harpsichord and the spinet, in which no force of

touch could lessen or strengthen the intensity of the sound produced, from the quills always striking the strings with nearly a like force; whereas in the pianoforte gradations of tone can be produced, the strings being put in vibration by means of small hammers connected by levers with the key or finger board, which hammers quit the strings directly they are struck, a damper falling down on the string the moment the finger is lifted from the key. Formerly the strings were all of thin wire; now the bass strings are thick and covered with a thin coil of copper wire; and the thickness, length, and tension of the strings all diminish from the lower to the upper notes. The grand pianoforte, which is somewhat triangular in shape, and has the wires running horizontally and parallel to the keys, has three strings to each of the upper and middle notes, generally two to the lower notes, and one to the lowest octave. In the square piano the strings are still placed in a horizontal position, but obliquely to the keys; while in the upright piano the strings are vertically from top to bottom of the instrument. From its great strength grand piano is the instrument best for the concert room; the square disappearing from the draw in this country, its place being now the upright. The invention of forte is now usually ascribed to Cristofori of Padua, and dates 1714, though claims have been made in favour of Schröter, a German organist, and Marius, a French harpsichord maker. The compass of the instrument, originally from four to five octaves, has now been extended to seven or even more.

Pisciculture has been practised from very early ages. It appears to have been in use in ancient Egypt, and was followed in China in early times on a very large scale. It was revived in this country by Mr Shaw of Drumlairig in 1633. One great point in modern pisciculture is the propagation and rearing of young fish in artificial ponds with the view of introducing fish previously not found in the locality. Salmon and trout ova have been sent from Britain, and successfully propagated in Australia and New Zealand. The art has now come into general favour and is widely followed, very many rivers having on their banks breeding and rearing establishments for the purpose of increasing the stock of fish in the streams. A very successful effort has been carried out at Stormontfield, near Perth, on the Tay. From Runingue, near Basel, on the Rhine, millions of ova are annually despatched to England, Germany, Spain, and other countries. The art is every year receiving greater de-

velopment, and promises to become yet an important department of commercial industry.

The male and female organs are united in the same individual, and the process of reproduction may be either sexual, by means of true ova, or non-sexual, by internal gemmation or transverse fission. The sub-order is divided into sections—*Rhabdocæla*, characterized by a straight, unbranching intestine, and a body elongated, rounded, or oval, and *Dendrocæla*, having a branched or arborescent intestine, and a flat, broad body.

This supposition may be adopted for short distances without leading to great errors; and it affords great facilities in calculation, as the place of the ship is found by the solution of a right-angled triangle. In plane sailing the principal terms made use of are the *course*, *distance*, *departure*, and *difference of latitude*, any two of which being given, the others can be found.—**Plane scale**, in navig. a scale on which are graduated chords, sines, tangents, secants, rhumbs, geographical miles, &c.—**Plane surveying**, the surveying of tracts of moderate extent, without regarding the curvature of the earth.—**Plane trigonometry**. A joiner's tool consisting of a smooth-soled stock, with an aperture, through which passes obliquely a piece of edged steel or a chisel, used in paring or

very straight; the *jointer*, still longer than the long plane, which is used for obtaining very straight edges; the *smoothing plane*

(7½ inches long), and *block plane* (12 inches long), chiefly used for cleaning off finished work, and giving the utmost degree of smoothness to the surface of the wood; the *compass plane*, which is similar to the

smoothing plane, but has its under surface convex, its use being to form a concave cylindrical surface. The foregoing are technically called *bench planes*. There is also a species of planes called *rebate planes*, the first of which is simply called the *rebate plane*, being chiefly used for making rebates. Of the sinking rebating planes there are two sorts, the *moving fillister* and the

sash fillister, the first for sinking the edge of the stuff next the workman, and the second for sinking the opposite edge. The *plough* is a plane for sinking a channel or groove in a surface not close to the edge of it. *Moulding planes* are for forming mouldings, and must vary according to the design. The *bead plane* is used for mouldings whose section is semicircular. Planes are also used for smoothing

The planets which revolve about the sun as their centre are called *primary planets*; those which revolve about other planets as their centre, and with them revolve about the sun, are called *secondary planets*, satellites, or moons. The primary planets are named Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus, and Neptune. Called also *major planets*. The minor planets are numerous small bodies called also planetoids or asteroids, which have been discovered since the beginning of the present century between the orbits of Mars and Jupiter. Mars, Jupiter, Saturn, Uranus, and Neptune, being without the earth's orbit, are sometimes

called the superior planets: Venus and Mercury, being within the earth's orbit, are called inferior planets. The family of major planets has also been subdivided into *intra-asteroidal* planets—Mercury, Venus, the Earth, Mars, and *extra-asteroidal* planets—Jupiter, Saturn, Uranus, and Neptune. This division is not arbitrary, since the characteristics of the planets travelling within the zone of asteroids differ in the most marked manner from the characteristics of the planets travelling outside that zone. Planets are so named from their motion or revolution in distinction from the fixed stars, from which they can be at once distinguished by their clear steady light, while the latter have a sparkling or twinkling appearance. See STARS.

Planetary (plan-et-ē-ri), *n.* [*Planet*, and *Gr. cōdes*, resemblance] One of a numerous group of very small planets revolving round the sun between the orbits of Mars and Jupiter, remarkable for the eccentricity of their orbits and the large size of their angle of inclination to the ecliptic. The diameter of the largest is not supposed to exceed 450 miles, while most of the others are supposed to be very much smaller. The known planetoids are upwards of 300 in number, and new members are being constantly discovered. Ceres was the first to be detected, being observed for the first time by Piazzi, an Italian astronomer, on 1st January, 1801, and since 1848 no year has passed without the discovery of new members. Called also *Asteroids*.

Plane-tree (plān'-trē), *n.* [*Fr. plane*, *plane-tree*, from *L. platanus*, the plane-tree.] A tree of the genus *Platanus*, nat. order *Platanaceae*. The oriental plane-tree (*P. orientalis*) is a native of Asia. It rises with a straight smooth branching stem to a great height, with palmate leaves and long pendulous peduncles, sustaining several heads of small close-sitting flowers. The seeds are downy, and collected into round, rough, hard balls. It is the handsomest of all the hardy deciduous trees in cultivation, and is perfectly suited to the climate of England. Its timber is fine-grained, hard, and well suited to such kinds of joiners' work as do not require strength, for which its brittleness renders it unsuitable. The occidental plane-tree (*P. occidentalis*), which grows to a great height, is a native of North America; it is called also *button-wood* and *button-tree*. Both species have the singular property of throwing off their old bark in hard plates of irregular size and form. In Scotland the same plane-tree is commonly given to the

eyebrow (*Acer pseudo-platanus*), which resembles the true plane in its foliage. See PLATANACEAE.

Plant (plānt), *n.* [*Fr. plante*, a plant, the sole of the foot, from *L. planta*, a plant, a twig, a slip, a cutting, a scion, the sole of the foot. The last is supposed to have been the original meaning, whence that of something slack or set in the ground, from root of *planta*, plain.] 1. One of the organisms which form the vegetable kingdom, a vegetable, an organized living body, destitute of sensation

and spontaneous motion, deriving its sustenance from the inorganic world, generally adhering to another body, and drawing from it some of its nourishment, and having the power of propagating itself by seeds or similar reproductive bodies. Some aquatic plants grow without being attached to any fixed body, and a few plants resemble animals in being capable of assimilating animal (and therefore organic) food. Some of the lower plants seem so nearly allied to some of the least highly developed animals that it is difficult to say where the series of plants ends and that of animals begins. (See extract below.) The principal organs of nutrition in plants are the roots and leaves, the former deriving nutriment from the soil, the latter from the atmosphere. By means of proper vessels the nourishing juices are distributed to every part of the plant. Solid matter cannot be directly imbibed by plants, it must first be dissolved in water or in a gaseous form. Carbonic acid is an important article of their nutriment, being absorbed from the air by the leaves, after which it is decomposed within the plant by the influence of sunlight, the carbon going to form vegetable substances, while the oxygen is exhaled into the air. The reproductive organs are those of which the flower is made up (see FLOWER), and the result of the functions which they perform is the fruit and seeds, which, under favourable circumstances, become developed into new individuals. The woody or dicotyledonous plants or exogens consist of three parts—the bark or exterior coat, which covers the wood; the wood, which is hard, and constitutes the principal part; and the pith or centre of the stem. In monocotyledonous plants or endogens the ligneous or fibrous parts and the pith or parenchymatous are equally distributed through the whole internal substance; and in such acotyledonous plants as fungi, seaweeds, &c., the substance is altogether parenchymatous. In its most general sense *plant* comprehends all vegetables, trees, shrubs, herbs, grasses, &c. Popularly the word is generally applied to the smaller species of vegetables.

What are the characters which induce us to place any given organism in either the animal or vegetable kingdom? What, in short, are the differences between animals and plants? Whilst all the preceding points have failed to yield a means of invariably separating animals from plants, a distinction which holds good without exception is to be found in the nature of the food taken respectively by each and in the results of the conversion of the same. As a broad rule, all *plants* are endowed with the power of converting inorganic into organic matter. The food of *plants* consists of the inorganic compounds, carbonic acid, ammonia, and water, along with small quantities of certain mineral salts. From these, and from these only, *plants* are capable of elaborating the proteinaceous matter or protoplasm which constitutes the physical basis of life. *Plants*, therefore, take as food very simple bodies, and manufacture them into much more complex substances.

On the other hand, no known animal possesses the power of converting inorganic compounds into organic matter, but all, mediately or immediately, are dependent in this respect upon *plants*. All animals, as far as is certainly known, require ready-made proteinaceous matter for the maintenance of existence, and this they can only obtain in the first instance from *plants*. Animals, in fact, differ from *plants* in requiring as food complex organic bodies, which they ultimately reduce to very much simpler inorganic bodies. The nutrition of animals is a process of oxidation or burning, and consists essentially in the conversion of the energy of the food into vital work, this conversion being effected by the passage of the food into living tissue. *Plants*, therefore, are the great manufacturers in nature, animals are the great consumers. Just, however, as this law does not invariably hold good for *plants*, certain fungi being in this respect animals; so it is not impossible that a limited exception to the universality of the law will be found in the case of animals also. H.A. Nicholson.

Platinum (plát'in-um), *n.* [See *PLATINA*.] *Sym. Pt.* At wt. 197.4. A metal discovered in 1741 in the mines of Chocó in Peru. It occurs only in the metallic state, associated or combined with various other metals, such as copper, iron, lead, titanium, chromium, gold, silver, palladium, rhodium, osmium, ruthenium, and iridium. It is usually in the form of rounded or flattened grains of a metallic lustre and white colour, mixed with sand and other alluvial depositions. Pure platinum has a white colour very much like silver, but of inferior lustre. It is the heaviest of known metals; its specific gravity, after forging, being about 21.25, and 21.5 in the state of wire. It is exceedingly ductile, malleable, tenacious, and difficult of fusion. It undergoes no change from the combined agency of air and moisture. It may be melted by voltaic electricity, or by the oxyhydrogen blow-pipe. Like iron it admits of being welded at a high temperature. It is not acted upon by any of the pure acids, but is dissolved by chlorine and nitro-muriatic acid, and is oxidised at high temperatures by pure potassa and lithia. It is capable of being hammered into plates of

extreme thinness, and Dr Wollaston succeeded in drawing out a wire of this metal to the thickness of $\frac{1}{16}$ th of an inch. From the unalterability of platinum at high temperatures, and its power of resisting the action of most chemical agents, it is much used for crucibles, evaporating dishes, and even alembics. It unites with most metals. It forms two series of compounds—*platino-*, represented by the chloride $PtCl_2$, and *platin-*, represented by the chloride $PtCl_4$. One of the most remarkable properties of platinum is its power of causing gum to enter into combination. When a perfectly clean plate of platinum is introduced into a mixture of oxygen and hydrogen, it will cause them to combine so as to form water, and often with such rapidity as to render the metal red hot. *Spongy platinum*, or the black powder of platinum, is most effective in producing this extraordinary result. A lot of hydrogen directed upon *spongy platinum* may be inflamed by the metal thus ignited, a property which has been applied to the construction of convenient instruments for producing light. *Spongy platinum*, metallic platinum in the form of a porous, dull, brown mass. It is obtained by heating the osmic-chloride of platinum. — *Platinum black powder*, a black powder obtained by decomposing a weak solution of chloride of platinum by the electric current.

The species are few in number, chiefly Eastern or Australian, and for the most part tropical.

Platycephalus (plăt'-tēr-fā-lus), *n.* [Gr. *platys*, broad, and *kephalē*, a head.] Broad-headed, an archaeological term applied to certain individuals remarkable for the antero-posterior flattening or platycephalism of the chinbone.

The human remains, which were described by Prof. Bush in the essay on the discovery published in the *Journal of the Ethnological Society*, January 1871, presented points of very high interest. On the whole, the skulls were rather above than below the present average cranial capacity, some of the leg bones were remarkable for the peculiar antero-posterior flattening or platycephalism of the chinbone. And this flattening was caused by the protrusion of the bone in front of the lower maxillary ridge, and not in any degree by its posterior expansion, which is the distinctive feature of the ribbed found in the caves of Cro-Magnon and of Gibraltar. The fact that these platycephalic leg bones were associated with others of the ordinary form, and for the most part belonging to the young, and probably to females, while the skulls were of the same type, proves that the character is not one of race, as M. Broca believed, but rather one peculiar to the individual and perhaps to the sex. *See H. Knight*

The intestinal canal of the *Platyrrhinus* has only a single orifice, and their nervous system is not very distinct. The division includes two parasitic orders—the *Tenacida* and the *Trematoda*; and one non-parasitic order, viz. the *Turbellaria*. A sub-order, however, of this last does not conform to the above definition, but their other characters are such as to forbid their separation.

It is found in the other Teutonic languages, but like other words beginning with *p* was probably borrowed, though the source is not clear. The A. Sax. word for *plough* was *suth* (still provincial in the forms *sull*, *sullow*), the O.N. *arthr* (from root of E. *ear*, L. *aro*, to plough).] 1. An implement drawn by animal or steam power, by which the surface of the soil is cut into longitudinal slices, and successively raised up and turned over. The object of the operation is to expose a new surface to the action of the air, and to render the soil fit for receiving the seed or harrowing, or for other operations of agriculture. *Ploughs* drawn by horses or oxen are of two kinds: those without wheels, commonly called *swing-ploughs*, and those with one or more wheels, called *wheel-ploughs*. The essential parts of both kinds of *plough* are, the beam, by which it is drawn; the stiles or handles, by which the ploughman guides it; the coulter, fixed into the beam, by which the furrow slice is cut; the share, by which the bottom of the furrow is cut and raised up; and finally, the mould-board, by which the furrow is turned over. The wheel-plough is merely the swing-plough with a wheel or pair of wheels attached to the beam for keeping the share at a uniform distance beneath the surface. Besides these two kinds there are *subsoil-ploughs*, *drill-ploughs*, *draining-ploughs*, &c.—*Double mould-board ploughs* are common *ploughs* with a mould-board on each side, employed for water-furrowing, earthing up potatoes, &c.—*Turn-wrest ploughs* are *ploughs* fitted either with two mould-boards, one on each side, which can be brought into operation alternately, or with a mould-board capable of being shifted from one side to the other, so that the furrow is always laid in the same direction. They are useful in ploughing hill-sides, as the furrows can all be turned towards the hill, thus counteracting the tendency of the soil to work downwards.—

Balance-ploughs are *ploughs* in which two sets of plough bodies and coulters are attached to an iron frame moving on a fulcrum, one set at either extremity, and pointing different ways. By this arrangement the balance-plough can be used without turning, the one part of the frame being raised out of the ground when moving in one direction, and the other when moving in the opposite. It is the front of the frame, or that farthest from where the driver sits, which is elevated, the ploughing apparatus connected with the after part being inserted and doing the work. *Balance-ploughs* are used in steam-ploughing. Generally two, three, or four sets of plough bodies and coulters are attached to either extremity, so that two, three, or four furrows are made at once.—*Steam-ploughs* on various principles have been introduced into Britain. Some are driven by one engine remaining stationary on the headland, which winds an endless rope (generally of wire) passing round pulleys attached to an apparatus called the 'anchor,' fixed at the opposite headland, and round a drum connected with the engine itself. Others are driven by two engines, one at either headland, thus superseding the 'anchor.' As steam-ploughing apparatus are usually beyond both the means and requirements of single farmers, companies have been formed at various places for hiring them out.—2. *Fig. tillage*; culture of the earth; agriculture. *Johnson*.—3. Name of various tools; as, (a) a joiner's instrument for grooving. See *PLANE*. (b) In *cloth manu.*, an instrument for cutting the flushing parts of the pile or nap of fustian. N.* *arlar* (from root of *Ir. ar*, *L. ara*, to plough).] 1 An implement drawn by animal or steam power, by which the surface of the soil is cut into longitudinal slices, and successively raised up and turned over. Balance-ploughs are ploughs in which two sets of plough bodies and coulters are attached to an iron frame moving on a fulcrum, one set at either extremity and pointing different ways. By this arrangement the *balance-plough* can be used without turning, the one part of the frame being raised out of the ground when moving in one direction, and the other when moving in the opposite. It is the front of the frame, or that farthest from where the driver sits, which is elevated, the ploughing apparatus connected with the after part being inserted and doing the work. *Balance-ploughs* are used in steam ploughing. Generally two, three, or four sets of plough bodies and coulters are attached to either extremity, so that two, three, or four furrows are made at once. *Steam ploughs* on various principles have been introduced into Britain. Some are driven by one engine remaining stationary on the headland, which winds an endless rope (generally of wire) passing round pulleys attached to an apparatus called the anchor, fixed at the opposite headland, and round a drum connected with the engine itself. Others are driven by two engines, one at either headland, thus separating the anchor. As steam-ploughing apparatus are usually beyond both the means and requirements of single farmers, companies have been formed at various places for hiring them out. - 2 *Ply* (ply) culture of the earth, agriculture. *Johnson.* 3 Name of various tools as, (a) a joiner's instrument for grooving. *See PLANE.* (b) In *slaid mow*, an instrument for cutting the finishing parts of the pile or nap of a fustian. With respect to their effects they have been divided into four classes, namely, irritant, narcotic, narcotico-acrid, and septic or putrescent. The poisons that affect the body through a puncture or abrasion may be derived from the mineral, the vegetable, or the animal kingdom, but, with a few exceptions, those derived from the mineral and vegetable kingdoms would act as efficiently if introduced into the stomach as if injected into the blood, while animal poisons are inert when introduced into the stomach, acting only by direct introduction into the blood. The most active poisons, in small doses, frequently form most valuable medicines. There are certain poisons, however, which are lethal in the smallest quantity. - 2. It is, in general, said of political economy, that its object is to ascertain the circumstances most favourable for the production of wealth, and the laws which determine its distribution among the different ranks and orders into which society is divided; and this definition seems quite unexceptionable, provided it be clearly understood that by *wealth* in this science is meant only those articles or products which require some portion of human industry for their production, acquisition, or preservation, and which, consequently, possess exchangeable value. The principal topics discussed by political economists are:—(1) The definition of wealth; (2) of productive and unproductive labour; (3) on the nature and measures of value; (4) on the rent of land; (5) the wages of labour; (6) the profits of capital; (7) the results of machinery; (8) the circulating medium or currency; (9) the nature and conditions of commerce or exchange of commodities.—*Political geography*. the means of subsistence. It prevails now
chiefly among the Buddhists of Central Asia
and of Ceylon, and is in the former area
strictly limited to the marriage of the woman
to two or more brothers. The surplus un-
married women are provided for in Lama

Polyp, **Polype** (po'lip), *n.* [L. *polypus*, from Gr. *polypous*—*poly*, many, and *pous*, a foot.] The name given to the members of a class of animals in the Radiata of Cuvier, associated together in virtue of the common character of a conical or cylindrical body, at one end of which is the mouth, surrounded by more or less numerous arms or tentacles, while the other extremity either serves as a sucker to attach the animal to some object, or, being prolonged like a thread down a hollow sheath, connects it with its fellow polyps of the same polypidom, which thus become a compound animal, the whole of whose parts are animated by a common principle of life and growth. As science progressed, however, it was discovered that under this common name were combined animals of various degrees of organization, three classes at least of which have been well ascertained and classified. The Polypi, therefore, had to be given up as a distinct class, and the members, with the exception of the Polyzoa, which were referred to the Mollusca, now form the sub-kingdom *Cœlentērata*, which comprises two classes, *Hydrozoa* and *Actinozoa*. (See **Cœlentērata**, **HYDROZOA**, **HYDRA**, **ACTINOZOA**.) The term *polyp*, however, is still indiscriminately applied to any of the *Cœlentērata*, but more especially to the *Hydra* or the sea-anemone. The name of *zoophytes* is also sometimes loosely applied to them.

The term is also not uncommonly applied to the very similar structures produced by the *seamats* and their allies (*Polyzoa*). The polypary-producing animals are propagated by budding, and live together in groups or colonies so associated that each group forms a compound animal, whose united coverings form a *compound polypary* (polypidom), which is their common home, and is at the same time the central stem or stock sustaining the whole. Each individual polyp thus lives in its own proper cavity in the common polypary, from which it protrudes its body, and into which it retracts it at pleasure. *Polypary* is used by those who desire to keep *polypary* for the *Actinozoa*.

Originally, the name given to a very hard stone, partaking of the nature of granite, susceptible of a fine polish, and consequently much used for sculpture. In the fine arts it is known as *Rosso Antiquo*, and by geologists as *Red Syenitic Porphyry*. It consists of a homogeneous felspathic base or matrix, having crystals of rose-coloured felspar, called oligoclase, with some plates of blackish hornblende, and grains of oxidized iron ore imbedded, giving to the mass a speckled complexion. It is of a red, or rather of a purple and white colour, more or less variegated, the shade being of all gradations, from violet to a claret colour. Egypt and the East furnish this material in abundance. It also abounds in Minorca, where it is of a red lead colour, variegated with black, white, and green. Pale red porphyry, variegated with black, white, and green, is found in separate nodules in Germany, England, and Ireland. The art of cutting porphyry as practised by the ancients appears to be now quite lost.—2. In geol. any unstratified or igneous rock in which detached crystals of felspar or some other mineral are diffused through a base of other mineral composition. Strictly speaking, however, the term ought to be restricted to such rocks as have a felspathic base. Its leading feature is what is known under the law of the three stages, which may be thus stated: every branch of knowledge passes

through three stages, viz. the theological, the metaphysical, and the positive. In the first stage, the phenomena of nature are attempted to be explained by reference to supernatural causes, by voluntary interferences, by prodigies, miracles, and the like. In the second stage supernatural and anthropomorphic causes give place to abstract, occult causes, scholastic entities, realized abstractions, and nature is interpreted a priori: the attempt is made to construe nature subjectively. In the third stage, man contents himself with ascertaining by observation and experiment the connections of phenomena, and so learning to connect each fact with its antecedent conditions. This is the method which has founded modern science, and which must take the place of metaphysics. Whatever is not capable of experimental verification must be rigorously excluded from science. The second conception of this system is the classification and co-ordination of the sciences. The theory of this classification requires us to advance from the simple to the complex, beginning with mathematics, and passing in turn to astronomy, physics, chemistry, biology, and sociology: these are the six fundamental sciences, each of which is necessary to the next following one. Thus sociology or the science of society is impossible without biology, the science of life, and the latter is impossible without the science of chemistry; chemistry, again, presupposes physics, which itself presupposes astronomy and mathematics.—*Positive pole* of a voltaic pile or battery. See *POLAR*.—*Positive terms*, in *logic*, those terms which denote a certain view of an object, as being actually taken of it.—*Positive quantity*, in *alg.* an affirmative or additive quantity, which character is indicated by the sign + (plus) prefixed to the quantity, called in consequence the *positive sign*. But the term attitude is more honourable than posture. Positions of the body which are forced, odd, ungainly, are called postures. Those which are noble, agreeable, and expressive, in which the expression of the countenance aids the pose of the limbs and body, are called attitudes. . . . Next to lithium it is the lightest metallic substance known, its specific gravity being 0.865 at the temperature of 60°. At 32° it is hard and brittle, with a crystalline texture; at 50° it becomes malleable, and in lustre resembles polished silver; at 150° it is perfectly liquid. At ordinary temperatures potassium may be cut with a knife. Potassium has a very powerful affinity for oxygen, which it takes from many other compounds. A freshly exposed surface of potassium instantly becomes covered with a film of oxide. The metal must therefore be preserved under a liquid free from oxygen, rock-oil or naphtha being generally employed.

Potato (pò'ta'tò), n. pl. Potatoes (pò'ta'tòs). [*Sp. patata*, *batata*, the name originally applied to the batatas or sweet-potato, and said to be a native Haytian word.] 1. The sweet-potato. See **BATATAS**. [This was the original application of the name, and it is in this sense that the word is generally to be understood when used by English writers down to the middle of the seventeenth century.]—2. The plant, or one of its esculent tubers, botanically known as *Solanum tuberosum*, a native of South America. The tubers of this plant constitute one of the cheapest and most nourishing species of vegetable food; it is the principal food of the poor in some countries, and has often contributed to prevent famine. It is supposed to have been introduced into the British dominions by Sir Walter Raleigh in the sixteenth century; but it came slowly into use, and even yet is not much cultivated in some countries of Europe. There are a great many varieties of the potato, arising from soil, culture, and other circumstances; these differ in the time of ripening, in their form, size, colour, and quality; and in general every district has its peculiar or favourite varieties, the names being quite arbitrary or local. Some degenerate and others improve by removal to another district. New varieties may be readily procured by sowing the seeds, which with care will produce tubers the third year, and a full crop the fourth.—*Potato apple*, the seed of the potato.—*Potato beetle*, *potato bug*. See **COLORADO BEETLE**.—*Potato disease*, *potato blight*, *potato murrain*, a disease affecting potatoes, first noticed in this country in 1845. The cause is a fungus or white mould (*Peronospora infestans*), whose spores first attach themselves to the leaves of the plants, betraying their presence by brown specks, each surrounded by a paler ring consisting of a white mould or fungus. The mould spreads with great rapidity, especially in moist warm weather, converting the green cells into brown, and destroying all before it. The spots soon become confluent, the evil extends to the stems, so that in a few days the whole becomes putrid. At last the tubers become affected with brown spots both on their substance and within their tissue, and decay sets in with less or more rapidity. It has been stated that the immediate cause of the disease is the death of the fungal threads, which on decomposition act as a putrescent ferment on tissues. Some assert that a more remote cause is an insect (*Eupterix*), which punctures the leaves, and so renders them a more ready prey to the fungus; while others hold that the plant has degenerated through being too long cultivated. Powdering the sets with flowers of sulphur, early planting, and the removal of the haulms as soon as

the disease appears, have been recommended as preventive or remedial measures. The starch in the tubers is not affected by it, so that as good potato starch is made from unrotted as from sound potatoes, and this manufacture, in years when the disease was severe, has been carefully developed. — *Potato mildew*, *Peronospora infestans*. See *Potato disease*, above. — *Potato rot*, a variety of the rot (*Ascozia rotacea*). — *Potato scab*, a fungus plant, the *Tuberaria candida*, found beneath the skin of the tuber of the potato, producing superficial cavities and pits. — *Potato starch*, a starch obtained from the potato, and called *English Arrow-root*. — *Potato sugar*, a species of sugar made factured from potato flour. — *Oil of potatoes*, a colourless substance obtained from spirits made from potatoes. It is somewhat oily in appearance, has a strong smell, at first pleasant, but afterwards nauseous, taste very acid. — *Sweet potato*, the *Solanum edule*. See *BATATAS*.

Power (pow'ér), n. [O *Fr* *puiss* (Med. *Fr* *puiss*), from an old infinitive *puiss*, from *L. L. potius* (It *potere*) to be able, used for *L. potens*, *potui*, *posse*, to be able, from *potis*, able, and *sum*, *esse*, to be, *potis* being akin to *Sci. potis*, a lord, a master, and *pot*, to rule, to govern. From *posse* come also *possible*, *potest*, &c.] 1 Ability to act, regarded as latent or inherent, the faculty of doing or performing something, that in virtue of which one can; capability of producing an effect; as, the power of voluntary motion, the power of heat to melt wax. — 2 Ability regarded as put forth or exerted, strength, force, or energy manifested in action, as, the power of steam in moving machinery, the power exerted by a hydraulic press. 3 Capacity, susceptibility, fitness to be acted on, called also *Passive Power*. The employment of the word in a passive sense is not strictly correct, but it has received general acceptance.

Power is, therefore, a word which may be both in an active and in a passive application, and, in psychology, we may apply it both to the active faculty and to the passive capacity of the mind.

It is usual to speak of a power of resources in matter, and of a power of resistance in mind. Such terms are *passive power*. *Johnson.*

4 Natural strength, animal strength, as, the power of the arm exerted in lifting, throwing, or holding. 5 Influence; prevalence upon, as, the power of the mind, of the imagination, of the fancy. 'The power of fancy.' *Shak.*

It never shall be said,
That this had power upon a spirit's soul.
Dryden.

6 Faculty of the mind as manifested by a particular mode of operation; as, the power of thinking, comparing, and judging, the reasoning power.

With which sense and bursts from the fumes of sleep
We slipped round in struggling power. *Shak.*

7 Ability, natural or moral; capability.

8 The employment of strength or influence among men; the exercise of control; command, the right of governing or actual government, dominion, rule, sway, authority. 'Nor palter'd with Eternal God for power.' *Tennyson.*

Power is no blessing in itself, but when it is employed to protect the innocent. *Scott.*

— 9 A power, a phrase applied to a political nation or party who hold office in a government. — 10 One who or that which exercises authority or control, a sovereign, whether emperor, king, or governing prince, or the legislature of a state, as, the great power; the smaller power. In this sense the state or nation governed is often included in the word power, as, Great Britain is a great power, the great power of Europe. — 11 A spirit or superhuman agent supposed to have dominion over some part of creation, a divinity, as, celestial power; the powers of darkness.

See under MECHANICAL. (b) The moving force applied to overcome some resistance, raise some weight, or produce the required effect. Thus the pressure of a weight, the elastic force of a spring, the muscular force of man and animals, wind, water, steam, are employed as powers in machinery. Power may be exerted for the purpose of producing or preventing motion; in the former case it is called a *moving power* or *force*, and in the latter a *resisting power* or *force*. (c) Mechanical advantage or effect, as, the power or mechanical advantage of the lever increases as the distance of the moving force (also termed the *power*) from the fulcrum increases, and diminishes as the distance of the weight or resistance from the same point increases. (d) Force or effect considered as resulting from the action of a machine. It is *work* and *up* the product arising from the multiplication of a number or quantity into itself. The first power of any number or quantity is the number or quantity itself. This when multiplied into itself becomes the square or second power of the quantity; this again multiplied by the original quantity becomes the cube or third power, this again multiplied by the original quantity becomes the fourth power; and so on. In like manner the successive powers of the quantity are, 1, 2, 3, 4, 5, &c. The numbers which indicate the powers of quantities are called the *indices* or *exponents*. Powers are considered as *negative* or *fractional*, according as they have negative or fractional exponents, as, a^{-1} , a^{-2} , a^{-3} , or $a^{\frac{1}{2}}$, $a^{\frac{1}{3}}$, $a^{\frac{1}{4}}$. — 14 In optics, the degree to which an optical instrument, as a telescope or microscope, magnifies the apparent linear or superficial dimensions of an object. — 15 A large quantity, a great number, as, a power of good things. equinoctial points, viz., from east to west, or contrary to the order of the signs. The equinoctial points do not retain the same position in the heavens, but have a slow retrograde motion at the rate of about 50" in a year, or about a degree in 71 642 years, the equator moving on the ecliptic while the ecliptic remains nearly coincident with the same fixed stars. This phenomenon is caused by the combined action of the sun and moon on the mass of matter accumulated about the earth's equator, and is called the precession of the equinoxes, because it makes the equinoxes succeed each other in less time than they would otherwise do. In consequence of the precession of the equinoxes, the longitudes and right ascensions of the heavenly bodies are continually increasing, and owing to the motion of the equator, which occasions that precession, their declinations also are altered. The precession of the equinoxes was discovered by Hipparchus a century and a half before the Christian era, though it is alleged that the astronomers of India had discovered it long before. At that time the point of the autumnal equinox was about 6° to the eastward of the star called Spica Virginia. In 1750, that is, about 1900 years after, this point was observed to be about 28° 21' westward of that star. Hence it appears that the equinoctial points will make an entire revolution in about 25,745 years.
